(54) Title: AN INTERNET RADIO COMMUNICATION SYSTEM

(57) Abstract: A communication system including mobile units distributed within a wireless communication network which are connected to a packet switched network (22) (e.g. Internet) via a proxy server (16) is disclosed. The proxy server converts unicast data packets coming from the packets switched network to multicast data packets being transmitted to the mobile units, and is also responsible for the overall management of the communication system.

WO 01/65817 A1

TITLE OF THE INVENTION

AN INTERNET RADIO COMMUNICATION SYSTEM

BACKGROUND OF THE INVENTIONField of the Invention

5 The present invention relates to a communication system, and more specifically relates to an Internet radio communication system including a plurality of mobile units (e.g., Internet radios) distributed within a wireless communication network.

Discussion of the Background

10 Currently, a user may connect to the Internet via a wireless network. Thus, the user may perform Internet activities without needing phone lines or cable connectors. For example, Figure 1 illustrates a Ricochet wireless MicroCellular Data Network (MCDN) developed by METRICOM. The Ricochet Network is a wide-area wireless system using spread-spectrum, packet-switching data technology and a frequency-hopping mesh architecture. The network
15 operates within the license-free (902-998 MHZ) range of the Radio Frequency (RF) spectrum, providing Ricochet subscribers with an affordable wireless solution and an alternative to standard telephone modems requiring phone line connections.

 As shown in Figure 1, the Ricochet wireless network includes a Ricochet wireless modem 100, which weighs about 13 ozs., attached to a laptop computer 102. The network also
20 includes shoebox-size radio transceivers 106, which are typically mounted to street lights or utility poles 104. The radio transceivers 106 require only a small amount of power from the

street light itself (connected with a special adapter) and are otherwise self-contained units (no other wiring or connections are necessary). In addition, the microcell radio transceivers 106 are strategically placed every quarter to half mile in a checkerboard pattern. Each radio transceiver 106 employs 162 frequency-hopping channels, and uses a randomly selected hopping sequence.

5 This allows for a very secure network, and enables many subscribers use of the network at the same time.

In addition, within a 20-square mile radius (containing about 100 radio transceivers), the Ricochet network includes Wired Access Points (WAPS) 108. WAPS 108 collect and convert the RF packets into a format for transmission to a T1 frame-relay connection to a wired IP

10 network backbone in a network interconnection facility 110.

The Ricochet network also includes a Ricochet name server 114, which resides on the Metricom backbone provided within the network interconnection facility 110 and provides connection validation and path information to the Ricochet modems 100. All connection requests go to the name server 114 for authorization before a connection can be made. When a

15 Ricochet modem 100 is first powered on, it sends a packet to the name server 114 containing the Ricochet modem's serial number. The name server 114 validates the subscription and the service request. If either the subscriber serial number is invalid or the requested service is not what the subscriber has purchased, the accessed request is denied. Only after the Ricochet modem 100 successfully registers with the name server 114 can the subscriber obtain Internet or phone line

20 service access to the Ricochet network. The router 107 and gateway 109 provide a connection between the Internet 112 and Ricochet wireless network.

Further, the Ricochet network distributes data between the Internet 112 and the laptop computer 102 using a unicast transmission method. Unicast transmission is designed to transmit

a single packet to a single destination and is inherently a point-to-point type of communication. If a node wants to send the same information to many destinations, it must send a copy of the same data to each recipient in turn. That is, the same information must be carried over the network multiple times.

5 One problem with a wireless network based on the unicasting transmission method is tens of thousands of subscribers simultaneously access the network, and many of these subscribers may be accessing the same information. Thus, in the unicast transmission method, there is a substantial replication of data packets. Accordingly, bandwidth usage is inefficient and some users may be prevented from accessing the network during peak times, for example. Further, the
10 name server 114 does not provide sufficient management and control operations for the network. Thus, the only way a user knows the system is at maximum capacity, for example, is by attempting to log onto the network and finding that he or she is unable to access the network.

SUMMARY OF THE INVENTION

15 Accordingly, one object of the present invention is to solve the above and other noted problems.

Another object of the present invention is to provide a novel Internet radio communication system which transmits data between a mobile unit (e.g., an Internet radio) and the Internet using a multicasting transmission method if more than one user selects a same
20 Internet service.

Yet another object of the present invention is to provide a proxy server for determining a system capacity of the network, managing the network, and converting unicast data packets to multicast data packets, for example.

To achieve these and other objects, the present invention provides a novel communication system including mobile units distributed within a wireless communication network which are connected to a packet switched network (e.g., the Internet) via a proxy server. The proxy server converts unicast data packets coming from the packet switched network to multicast data packets being transmitted to the mobile units, if more than one mobile unit requests a same service (e.g., a same Uniform Resource Locator - URL). The proxy server is also responsible for the overall management and control of the communication system.

BRIEF DESCRIPTION OF THE DRAWINGS

A more complete appreciation of the invention and many of the attendant advantages thereof will be readily obtained as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings, wherein:

Figure 1 is a schematic of a conventional wireless network;

Figure 2 is a schematic of an Internet radio communication system according to an embodiment of the present invention;

Figure 3 is a schematic of display regions and a keypad of an Internet radio according to an embodiment of the present invention;

Figure 4 is a block diagram illustrating components of the Internet radio according to an embodiment of the present invention;

Figure 5 is a schematic of a multicasting operation according to an embodiment of the present invention;

Figure 6 is a flowchart illustrating operational steps performed for communication between the Internet and mobile units according to an embodiment of the present invention;

Figure 7 is a flow chart illustrating operational steps of a proxy server connected between the Internet and mobile units according to an embodiment of the present invention; and

5 Figure 8 is a schematic illustration of a computer system (e.g., proxy server) for implementing the method of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring now to the drawings, wherein like reference numerals designate identical or
10 corresponding parts throughout the several views, Figure 2 is a schematic of an Internet radio communication system 1 according to the present invention. As shown, the Internet radio communication system 1 includes a wireless communication network 12. In contrast to the conventional network of Figure 1, the wireless network 12 according to an embodiment of the present invention is configured to receive and transmit multicast data packets. The wireless
15 network 12 includes, but is not limited to, radio transmitters 2, a radio tower 10, a wireless Personal Digital Assistant 6 (PDA), a laptop computer 8, and an Internet radio 4. The radio tower 10, a gateway 14, a proxy server 16 and a router 20 allow connection of the wireless network 12 to the Internet 22. The Internet 22 is also connected to at least one source 24, which includes a data device 26, via a router 21.

20 The communication system according to an embodiment of the present invention includes at least the following novel features: 1) an Internet radio, 2) a proxy server which provides a variety of control mechanisms and management functions of the communication system, and 3) communication is performed by multicasting. Each of these features will now be described.

Internet radio

One example of the Internet radio 4 according to an embodiment of the present invention is shown in Figure 3. The Internet radio 4 includes a first display region 32 for displaying an advertisement, for example, and a second display region 34 for inputting information corresponding to a requested Internet service. For example, the second display region 34 includes the term "MCI WORLDCOM" which is a hyperlink to the Internet website "www.wcom.com." The hyperlink may be input into the second display region 34 using a keypad 36. The keypad 36 includes a plurality of alpha and numerical keys 37, a tuner 44, a select button 42, an update button 41 and a microphone 43. The user may also enter an entire website address using the keypad 36. The Internet radio 4 may also be voice activated. That is, a user may input a hyperlink or entire website address using the microphone 43. Once the desired website or hyperlink is input, the user may press the select button 42 to select that website. The user may also use the tuner 44 to scroll through a predetermined list of websites. Further, the tuner 44 is shown as a dial, however, the tuner 44 may also be "Up and Down" arrow keys allowing the user to scroll through a list of predetermined websites. The update button 41 may be selected to display a list of predetermined websites currently available (this feature will be discussed in more detail later).

Further, the Internet radio 4 may be installed in a dashboard of an automobile. Thus, the user may listen to a baseball game that is not locally transmitted. This differs from a typical radio, which is limited to receiving only those baseball games which are transmitted in a respective city. Further, the keypad 36 may also be foldably connected to the first and second display regions 32, 34 such that the keypad 36 covers the display regions 32, 34.

Figure 4 is a block diagram illustrating components of the Internet radio 4. As shown, the Internet radio 4 includes an antenna 72, a radio interface 60, an interface controller 62, a memory 64, a CPU 66, a digital signal processor 69, a display controller 68 and a display 70.

Proxy Server

The proxy server 16 provides a variety of control mechanisms and management functions of the communication system according to the present invention. For example, the proxy server 16 acts as a local depository of cached radio programs, and provides directory services of current offerings (e.g., live radio programs). A "live" radio program is, for example, a baseball game that is currently being played and thus a user may listen to the "live" radio program. The proxy server 16 also acts as a bridge between unicast sources on the Internet side and multicast listeners on the wireless network. That is, the proxy server 16 is configured to convert unicast data packets coming from the Internet side to multicast data packets for transmission to the mobile units. The proxy server 16 also decides whether a sufficient network capacity exists to process a user's request. This may be achieved by statistically determining how many channels are currently being used versus how many channels are available. The proxy server 16 may also cache data coming from the Internet to smooth out transmission (i.e., in a case the transmission speed of the Internet is different than for the wireless network).

In an exemplary embodiment of the present invention, the proxy server 16 continuously receives information from the source 24 of the Internet 22 for a predetermined list of channels. A user may then select the update push button 41 of the Internet radio 4 to inquire about available channels. The proxy server 16 then transmits the predetermined list of channels that it is continuously receiving to the Internet radio 4. The user may then scroll through the

predetermined list of channels on the second display region 34 and select a desired channel via the select button 42 (see Figure 3). The channels currently available may also be transmitted to Internet radio 4 when the Internet radio 4 is first turned on, or periodically, for example.

In another exemplary embodiment of the present invention, the user may "dial on demand" a particular website that he or she wishes to receive. The particular website (or hyperlink) may be entered using the keypad 36 or microphone 43 of the Internet radio 4 as discussed above. In this example, the proxy server 16 receives and processes the request from the Internet radio 4. A list of "favorite" channels may also be stored in the memory 64 of the Internet radio 4 and the user may then scroll through this list.

Multicasting

A description of multicasting according to the present invention will now be given. IP multicast is an extension of IP, and is a mechanism for transmitting IP datagrams from one source to many destinations in a LAN or WAN. In an embodiment of the present invention, the IP datagrams are transmitted to mobile units (e.g., Internet radios, PDA's, etc.), which are distributed within a wireless network (rather than a hard wired LAN or WAN, for example). Multicast data packets are addressed to a group of mobile units, rather than to a single mobile unit; it is the responsibility of the network to forward the packets to only the mobile units that need to receive them. The mobile units which request the same Internet service are designated as a specific group. Thus, with IP multicast, the proxy server 16 may send one copy of the information to a plurality of mobile units. In addition, multicasting is connectionless, which means that a multicast datagram is neither guaranteed to reach all members of the group nor guaranteed to arrive in the same order as it was sent. The protocol delivers a multicast datagram

to the destination group members on a best-effort basis. However, upper layer protocols (e.g., TCP and UDP) introduce reliable delivery services. Further information about multicasting may be found in MARCUS GONCALVES ET AL., IP Multicasting: Concepts and Applications, (McGraw Hill, 1999), which is incorporated by reference in its entirety.

5 For example, as shown in Figure 5, the proxy server 16 may send only one copy of requested information (denoted as "a" in the figure) to the radio transmitters 2a, 2b and 2c via the gateway 14 and radio tower 10. The radio transmitters 2a, 2b, 2c, 2d, and 2e are configured as multicasting "routers." The radio transmitter 2c then distributes a copy to each of the Internet radios 4a, 4b, and 4c. The Internet radios 4a, 4b and 4c are illustrated as a same group because
10 they requested the same Internet service (e.g., channel number 2 corresponding to a baseball game, for example). An Internet radio 4d which requests a channel number 3, for example, does not receive the baseball game. Thus, as can be seen, multicasting saves a considerable amount of bandwidth needed to operate the communication system. If unicasting was used, a separate copy would be sent to each Internet radio. That is, in the link between the base station 10 and the
15 radio transmitter 2a, for example, three copies of data "a" would be sent (i.e., one copy for each of the Internet radios 4a, 4b and 4c which requested the same Internet service).

As previously discussed, the proxy server 16 is configured to convert unicast data packets coming from the Internet to multicast data packets going to the mobile units. To achieve this, the proxy 16 converts the address scheme of unicast to multicast.

20 The destination address field of the IP header in a multicast IP data packet includes a Class D group address instead of a Class A, B, or C IP address. A Class D address is an IP address and has the format 224.0.0.0 - 239.255.255.255. In Class D addressing, the lower 256 entries of the address range are reserved for administrative functions and system-level routing

chores. The middle range is for use by end-user multicast applications within groups, intranets, and the Internet. The upper range of the Class D address set is reserved for locally administered or site-specific multicast applications.

Mobile units (e.g., Internet radios 4, PDA's 6, etc.) willing to receive multicast messages
5 (data packets) need to inform their immediately-neighboring multicast-aware radio transceiver 2 that they are interested in receiving multicast messages sent to certain multicast groups. This way, each mobile unit can become a member of one or more multicast groups and receive the multicast packets sent to those groups. The protocol through which mobile units communicate this information with their local radio transceiver 2 is called Internet Group Management
10 Protocol (IGMP). The IGMP is also used by the radio transceiver 2 to periodically check whether the known group members are still active.

Turning now to an operation of the communication system according to the present invention. A description will be given with respect to a user using the Internet radio 4, however, the user may also use the wireless PDA 6 or the laptop computer 8, for example. Referring to
15 Figure 6, after the Internet radio 4 is turned on, the Internet radio 4 accesses to the wireless network 12 (step S2). The proxy server 16 provides connection validation and path information, and all connection requests go through the proxy server 16 for authorization before a connection can be made. When the Internet radio 4 is first powered on, it sends a packet to the proxy server 16 including the Internet radio's 4 serial number. The proxy server 16 then validates the
20 subscription and the service request. If either the subscription serial number is invalid or the service being requested is not what the subscriber has purchased, the access request is denied. Only after the Internet radio 4 successfully registers with the proxy server 16, can the subscriber obtain Internet service on the wireless network. The proxy server 16 also determines in step S4

what type of plan the user has subscribed to (e.g., "dial on demand" or a "standard package").

The type of plan may be determined from a table stored in the proxy server, which includes the address of the mobile unit and the type of plan, for example. Then, the proxy server 16 processes the requests of the Internet radio (step S6).

5 Figure 7 is a flowchart illustrating operational steps of the proxy server 16. After the Internet radio 4 has accessed the wireless network 12 and their proxy server 16 has determined the type of plan the Internet radio 4 has subscribed to, etc., the user may request a desired Internet service. Then, in step S10, the proxy server 16 determines whether the requested service is currently offered (i.e., whether the requested channel is "live" or prerecorded).

10 If the desired Internet service is not currently offered ("No" in step S10), the proxy server 16 informs the user of available options (step S24). The available options may include, but are not limited to, a list of currently in-progress multicasts, a most recent multicast, the five most popular multicasts, etc. The proxy server 16 then determines whether the option selected by the user has been selected by another user (step S25). If the option has been selected by another
15 user, the proxy server 16 executes step S12 and the appropriate following steps. If the user is the first to select an option, the proxy server 16 determines whether the requested option (i.e., Internet service) is cached by the proxy server 16 (step S26). If the service is cached ("Yes" in step S26), the proxy server 16 transmits in stream mode the requested Internet service to the user (step S30). If the requested Internet service is not cached by the proxy server 16, the proxy
20 server 16 retrieves the requested Internet service from the source 24 of the Internet 22 (step S28) and then transmits this retrieved file to the user (step S30).

 Returning now to step S10. If the requested Internet service is currently offered, such as a baseball game currently being played ("Yes" in step S10), the proxy server 16 determines

whether this is the first user to request the Internet service (step S12). If it is not the first user ("No" in step S12), the proxy server 16 transmits in streaming mode the requested Internet service to the user (step S30). That is, multicasting has previously been established for the first user, and thus the currently offered Internet service is being transmitted via multicasting.

5 Therefore, the newly joined multicast ready Internet radio will receive the transmitted multicast data packets. If it is the first user to request the Internet service ("Yes" in step S12), the proxy server 16 establishes multicasting (step S14) and then transmits the requested Internet service to the user. Further, in this example, the proxy server establishes multicast communication for the first user. However, it is possible to establish multicast communication only if more than one
10 user requests a same Internet service. That is, it is possible to transmit in unicast (no conversion is necessary) if only one user has requested an Internet service. The proxy server 16 may determine if more than one user has requested a same service by maintaining a table including an address of the mobile unit, the type of plan, and the requested service, for example. Thus, the proxy server 16 may read this table and determine if more than one user (i.e., mobile unit) has
15 requested the same Internet service. The proxy server 16 may also provide the user with the capability of indexing a particular multicast. For example, the user may listen to the third quarter of a football game by indexing the multicast to that quarter.

In addition, data transmitted between the Internet and mobile units may be, but is not limited to, video, audio, text, graphic, still video and programmatic data (e.g., software updates
20 and any other information representable in digital form).

All or a portion of the invention may be conveniently implemented using conventional general purpose computers or microprocessors programmed according to the teachings of the present invention, as will be apparent to those skilled in the computer art. Appropriate software

can be readily prepared by programmers of ordinary skill based on the teachings of the present disclosure, as will be apparent to those skilled in the software art.

Figure 8 is a schematic illustration of a computer system 100 for implementing the method of the present invention. The computer system 100 includes a computer housing 102 for housing a mother board 104, which contains a CPU 106, a memory 108 (e.g., random access memory (RAM) dynamic RAM (DRAM), static RAM (SRAM), synchronous DRAM (SDRAM), flash RAM, read-only memory (ROM), programmable ROM (PROM), erasable PROM (EPROM), and electrically erasable PROM (EEPROM)), and other optional special purpose logic devices (e.g., application specific integrated circuits (ASICs)) or configurable logic devices (e.g., generic array of logic (GAL) or reprogrammable field programmable gate arrays (FPGAs)). The computer system 100 also includes plural input devices, such as a keyboard 122 and a mouse 124, and a display card 110 for controlling a monitor 120. In addition, the computer system 100 further includes a floppy disk drive 114; other removable media devices (e.g., a compact disc 119, a tape, and a removable magneto-optical media); and a hard disk 112, or other fixed, high density media drives, connected using an appropriate device bus (e.g., a small computer system interface (SCSI) bus, and enhanced integrated device electronics (IDE) bus, or an ultra-direct memory access (DMA) bus). The computer system 100 may additionally include a compact disc reader 118, a compact disc reader-writer unit, or a compact disc juke box, each of which may be connected to the same device bus or another device bus. Although the compact disc 119 is shown in a CD caddy, the compact disc 119 can be inserted directly into CD-ROM drives which do not require caddies.

As stated above, the system includes at least one computer readable medium or memory programmed according to the teachings of the invention and for containing data structures,

tables, records, or other data described herein. Examples of computer readable media are compact discs, hard disks, floppy disks, tape, magneto-optical disks, PROMs (EPROM, EEPROM, Flash EPROM), DRAM, SRAM, SDRAM, etc. Stored on any one or on a combination of computer readable media, the present invention includes software for controlling
5 both the hardware of the computer 100 and for enabling the computer 100 to interact with a human user (e.g., a consumer). Such software may include, but is not limited to, device drivers, operating systems and user applications, such as development tools. Such computer readable media further includes the computer program product of the present invention for performing all or a portion (if processing is distributed) of the processing performed in implementing the
10 invention. The computer code devices of the present invention can be any interpreted or executable code mechanism, including but not limited to scripts, interpreters, dynamic link libraries, Java classes, and complete executable programs. Moreover, parts of the processing of the present invention may be distributed for better performance, reliability, and/or cost.

Obviously, numerous modifications and variations of the present invention are possible in
15 light of the above teachings. It is therefore to be understood that within the scope of the appended claims, the invention may be practiced otherwise than as specifically described herein.

Claims:

1. A communication system, comprising:

a mobile unit distributed within a wireless communication network and configured to request a service of a packet switched network from a data source on the packet switched network; and

a proxy server connected between the packet switched network and the wireless communication network and configured to convert unicast data packets coming from the packet switched network to multicast data packets for transmission to the mobile unit.

2. The system according to Claim 1, wherein the proxy server is configured to determine whether a requested service is currently offered.

3. The system according to Claim 2, wherein the proxy server is configured to provide a user using the mobile unit a plurality of available options if the requested service is not currently offered.

4. The system according to Claim 3, wherein the plurality of options include at least one of 1) a list of currently in-progress multicasts, 2) a most recent multicast, and 3) a list of most popular multicasts.

5. The system according to Claim 1, wherein the proxy server is configured to cache a plurality of services from the data source on the packet switched network.

6. The system according to Claim 1, wherein the proxy server is configured to continuously receive a plurality of currently offered services.

7. The system according to Claim 1, wherein the proxy server is configured to determine a current system capacity of the communication system and to notify the mobile unit if a requested service cannot be provided.

8. The system according to Claim 1, wherein the mobile unit comprises at least one of an Internet radio, a Personal Digital Assistant (PDA), and a laptop computer.

9. The system according to Claim 1, wherein the mobile unit includes:

an input mechanism configured to input a requested service; and

a second display region configured to display an advertisement and the requested service.

10. The system according to Claim 9, wherein the input mechanism is foldably connected to the display so that the input mechanism covers the display.

11. The system according to Claim 9, wherein the input mechanism comprises at least one of 1) a keypad configured to input the requested service, 2) a dial configured to scroll through a list of predetermined services, 3) UP and DOWN arrow keys configured to scroll through the list of predetermined services, 4) a selecting mechanism configured to select one of the predetermined services and 5) a voice activated mechanism.

12. The system according to Claim 1, wherein the mobile unit is configured to store a predetermined list of available services transmitted from the proxy server.

13. The system according to Claim 12, wherein the mobile unit receives the
5 predetermined list of available services when at least one of the following conditions occur: 1) the mobile unit is powered ON, 2) at predetermined time intervals, and 3) when requested by a user.

14. The system according to Claim 1, wherein data transmitted between the source on the
10 packet switched network and the mobile unit includes at least one of 1) video, 2) audio, 3) text, 4) graphic, 5) still video, and 6) programmatic data.

15. The system according to Claim 1, wherein the packet switched network is an Internet Protocol based network.

16. The system according to Claim 15, wherein the Internet Protocol based network is the Internet.

17. The system according to Claim 1, further comprising additional mobile units.

18. A communication method, comprising the steps of:

20 establishing a connection between a packet switched network and a mobile unit distributed within a wireless communication network;

requesting a service from a data source on the packet switched network; and
converting, via a proxy server connected between the packet switched network and the
wireless communication network, unicast data packets coming from the packet switched network
to multicast data packets for transmission to the mobile unit.

5

19. The method according to Claim 18, further comprising the step of:
determining, via the proxy server, whether a requested service is currently offered.

10

20. The method according to Claim 19, further comprising the step of:
informing a user using the mobile unit about a plurality of available options if the
requested service is not currently offered.

15

21. The method according to Claim 20, wherein the plurality of options include at least
one of 1) a list of currently in-progress multicasts, 2) a most recent multicast, and 3) a list of
most popular multicasts.

20

22. The method according to Claim 18, further comprising the step of:
caching, via the proxy server, a plurality of services from the data source on the packet
switched network.

23. The method according to Claim 18, further comprising the step of:
continuously receiving, via the proxy server, a plurality of currently offered services.

24. The method according to Claim 18, further comprising the steps of:
determining, via the proxy server, a current system capacity of the communication
system; and
notifying the mobile unit if a requested service cannot be provided.

5

25. The method according to Claim 18, wherein the mobile unit comprises at least one of
an Internet radio, a Personal Digital Assistant (PDA), and a laptop computer.

10

26. The method according to Claim 18, wherein the mobile unit includes:
an input mechanism configured to input a requested service; and
a display configured to display an advertisement and the requested service.

15

27. The method according to Claim 26, wherein the input mechanism is foldably
connected to the display so that the input mechanism covers the display.

20

28. The method according to Claim 26, wherein the input mechanism comprises at least
one of 1) a keypad configured to input the requested service, 2) a dial configured to scroll
through a list of predetermined services, 3) UP and DOWN arrow keys configured to scroll
through the list of predetermined services, 4) a selecting mechanism configured to select one of
the predetermined services, and 5) a voice activated mechanism.

29. The method according to Claim 18, further comprising the step of:
storing, via the mobile unit, a predetermined list of available services transmitted from
the proxy server.

30. The method according to Claim 29, further comprising the step of:

receiving, via the mobile unit, the predetermined list of available services when at least one of the following conditions occur: 1) the mobile unit is powered ON, 2) at predetermined time intervals, and 3) when requested by a user.

31. The method according to Claim 18, wherein data transmitted between the source on the packet switched network and the mobile unit includes at least one of 1) video, 2) audio, 3) text, 4) graphic, 5) still video, and 6) programmatic data.

32. The method according to Claim 18, wherein the packet switched network is an Internet Protocol based network.

33. The method according to Claim 32, wherein the Internet Protocol based network is the Internet.

34. The method according to Claim 18, wherein the establishing step is performed with additional mobile units.

35. A computer-readable medium carrying one or more sequences of one or more instructions for synchronizing a database of source documents. the one or more sequences of one or more instructions including instructions which, when executed by one or more processors, cause the one or more processors to perform the steps of:

establishing a connection between a packet switched network and a mobile unit distributed within a wireless communication network:

requesting a service from at least one data source on the packet switched network; and

converting, via a proxy server connected between the packet switched network and the wireless communication network, unicast data packets coming from the packet switched network to multicast data packets for transmission to the mobile unit.

36. The computer-readable medium according to Claim 35, wherein the one or more processors further perform the step of:

determining, via the proxy server, whether a requested service is currently offered.

37. The computer-readable medium according to Claim 36, wherein the one or more processors further perform the step of:

informing a user using the mobile unit about a plurality of available options if the requested service is not currently offered.

38. The computer-readable medium according to Claim 37, wherein the plurality of options include at least one of 1) a list of currently in-progress multicasts, 2) a most recent offered multicast, and 3) a list of most popular multicasts.

39. The computer-readable medium according to Claim 35, wherein the one or more processors further perform the step of:

caching, via the proxy server, a plurality of services from the data source on the packet switched network.

 40. The computer-readable medium according to Claim 35, wherein the one or more
5 processors further perform the step of:

 continuously receiving, via the proxy server, a plurality of currently offered services.

 41. The computer-readable medium according to Claim 35, wherein the one or more
processors further perform the steps of:

10 determining, via the proxy server, a current system capacity of the communication
system; and

 notifying the mobile unit if a requested service cannot be provided.

 42. The computer-readable medium according to Claim 35, wherein the one or more
15 processors further perform the step of:

 receiving, via the mobile unit, a predetermined list of available services from the proxy
server when at least one of the following conditions occur: 1) the mobile unit is powered ON, 2)
at predetermined time intervals, and 3) when requested by a user.

 43. The computer-readable medium according to Claim 35, wherein data transmitted
20 between the source on the packet switched network and the mobile unit includes at least one of
1) video, 2) audio, 3) text, 4) graphic, 5) still video, and 6) programmatic data.

INTERNATIONAL SEARCH REPORT

In national application No.
PCT/US01/06370

A. CLASSIFICATION OF SUBJECT MATTER

IPC(7) : H04M 3/42

US CL : 370/349

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 370/349, 345, 328, 310 ; 455/414, 445.

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

EAST

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	US 6, 161, 008 A (LEE et al) 12 December 2000, Fig. 1 col 4 lines 10-61, col 20 lines 18-56	1-8, 12-20, 25-27, 29, 31-37, 39-43.
Y	US 6, 181, 697 B1 (NURENBERG et al) 30 January 2001 , Fig. 1, col 6 lines 48-67, col 7 lines 1-47.	1-8, 12-20, 25-27, 29, 31-37, 39-43.

☐ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

* Special categories of cited documents:	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A" document defining the general state of the art which is not considered to be of particular relevance	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E" earlier document published on or after the international filing date	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"&" document member of the same patent family
"O" document referring to an oral disclosure, use, exhibition or other means	
"P" document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search

07 APRIL 2001

Date of mailing of the international search report
